Bootstrap & Codeigniter

CI and Bootstrap Assignment

K.A.H.C.Kumarasinghe | 18000878 |

What is codeigniter and bootstrap?

CodeIgniter is PHP driven framework but it's not a PHP substitute. Bootstrap is the most popular css framework for developing responsive and mobile-first websites.

Implementation of CRUD operation.

- 1. First we should create a database in localhost using PhPMyAdmin.
- 2. Next build a controller inside the application/controller folder. To create a controller I create a file called member_details.php inside the above folder.
- 3. Inside that file CI_Controller class must be extended and controller name and file name should be the same.
- 4. Next create a model which is the class designed to work with information in the database. It must be create inside the application/models directory. Here I create member_details_model.php inside above directory.
- 5. Then connect the database with codeigniter by editing application/config/database.php file.
- 6. Next we should save data in the database. For this create a file in view directory name as member_details_create.php.

7. After that create a function called savedata() inside the controller.

```
| Temper | X | Temper | Action contents | X | Temper | Temper | X | Tempe
```

8. Then create a function called saverecord() inside the model where the query would executed.

9. To retrieve date in the database create 3 functions called displaydata(), displaydelete(), displayupdate() inside the controller and create a function called display_users()inside the member_details_model.php

```
Homephp X member_details_recete.php X member_details_model.php X member_details_model.php X member_details_model.php X member_details_display.php X v

public function displaydata()
{
    $result['data'] = $this-> member_details_model-> display_users();
    $this-> load-> view('member_details_model-> display_users();
}

public function displaydelete()
{
    $result['data'] = $this-> member_details_model-> display_users();
    $this-> load-> view('member_details_delete', $result);
}

public function displayupdate()
{
    $result['data'] = $this-> member_details_model-> display_users();
    $this-> load-> view('member_details_model-> display_users();
    $this-> load-> view('
```

10. To delete date in the database create a function called deletedata() inside the controller.

```
Homephp x | member_details_create.php x | member_getails.php x | member_details_model.php x | member_de
```

11. To update data in the database create a function called updatedata() inside the controller.

```
## Home.php x member_details_create.php x members_report.php x member_details.php x member_details_model.php x member_details_display.php x for member_details_model.php x member_details_model.php x member_details_display.php x for member_ID is for member_ID is
```

12. Then create a functions called update_users() inside the member_details_model.php

```
Homephp x member_details_create.php x members_report.php x member_details.php x member_details_model.php x member_details_display.php x v

27
28
public function update_users($Member_ID, $First_Name, $Last_Name, $IGN, $Contact_Number, $Primary_Game)

{
    $query = $this-> db-> query("update member_details SET first_name='$First_Name', last_name='$Last_Name', ign='$IGN', contact_number='$Contact_Number', primary_game='$Primary_Game' where Member_ID='".$

31
}
```

13. Then create a function inside the member_details_model.php named as delete_users(\$Member_ID).

After completing above steps we can save, delete, update and retrieve data.

14. To generate pdf report create new library called "pdf_Library.php", new controller called "pdf_Controller" and new model called "pdf_Model".

Lessons that I learn

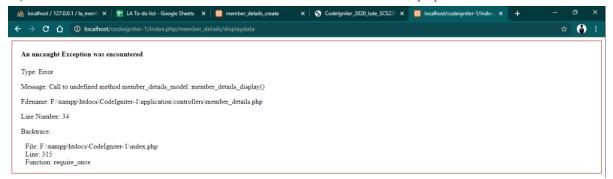

- Get familiar with the codeigniter and bootstrap framework.
- Get clear idea about what is controller? What is model? And what is view?
- How to implement CRUD operations in codeigniter.
- How to add bootstrap to the codeigniter.
- How we connect controller and model each other.
- How to view the page on the web browser.
- How to generate report in pdf format using data in databse.

Problem that I faced

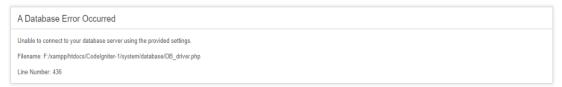

Error - Call to undefined function redirect()
 After adding \$this->load->helper('url') into the controller the error gets solved.

- 2. parseError- syntax errors
- 3. Error Undefined Variable
- 4. Error- call to undefined method in member_details_model.php

5. Database errors :

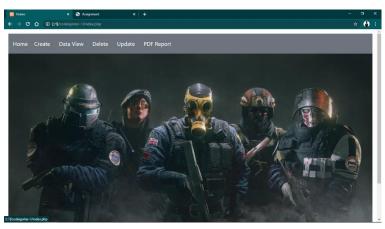

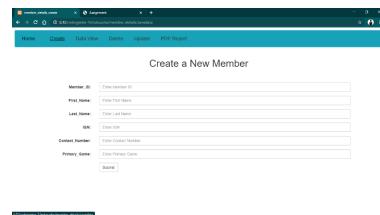

6. 404- Object Not Found!

7. When creation report I got the errors in creating library, controller and model. To solve those errors I followed some tutorial videos.

Screenshots of My Application
